STELLAR EVOLUTION. I. THE APPROACH TO THE MAIN SEQUENCE*

ICKO IBEN, JR.

California Institute of Technology, Pasadena, California

Received August 18, 1964; revised November 23, 1964

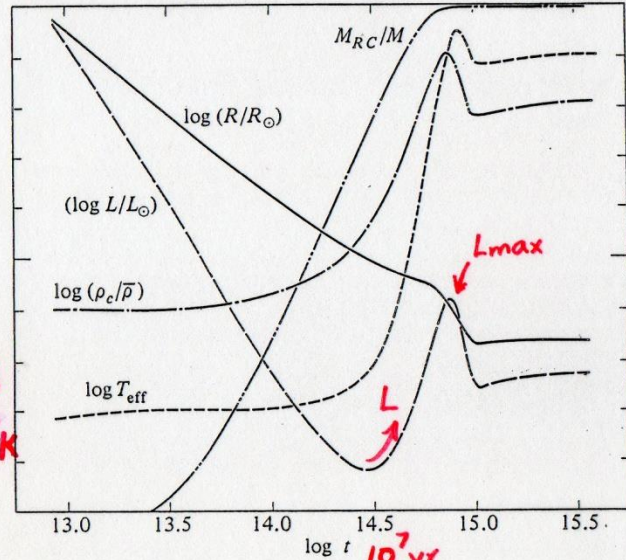

ABSTRACT

The manner in which nuclear reactions replace gravitational contraction as the major source of stellar luminosity is investigated for model stars of population I composition in the mass range $0.5 < M/M_{\odot} < 150$. By following in detail the depletion of C^{12} from high initial values down to values corresponding to equilibrium with N^{14} in the C-N cycle, the approach to the main sequence in the Hertzsprung-Russell diagram and the time to reach the main sequence, for stars with $M \geq 1.25 M_{\odot}$, are found to differ significantly from data reported previously.

1 M_{\odot}

$$L \equiv L_{\text{nuc}} + L_{\text{grav}}$$

M_{RC}/M	$\log (R/R_{\odot})$	$\log (\rho_c/\bar{\rho})$	$\log T_{\text{eff}}$	$\log (L/L_{\odot})$
1.0	+0.6	2.0	3.78	+0.6
0	-0.4	0	3.58	-0.4

$\log T_{\text{eff}} \sim 3.62$
 $T_{\text{eff}} \sim 4200\text{K}$

$\tau \sim 14.5$
 $L \uparrow$
 \therefore nuclear reactions
 $H^1 \rightarrow H^2 \rightarrow He^3$
 $C^{12} \rightarrow N^{13} \rightarrow C^{13}$
 $\quad \quad \quad \rightarrow N^{14}$
 σ_b
 Rest reactions do not operate
 \Rightarrow temporary

M_{CC}/M	$\log \rho_c$	$\log T_c$	L_g/L
0.20	2.0	7.25	1.0
0	1.0	6.75	0

\Rightarrow convective core until C^{12} depleted (p-p chain more important)

$$L_{\text{nuc}} = \int_0^M \epsilon dM_r$$

r	P	ρ	T	L_r
$0.882 R_{\odot}$	1.647×10^{17}	85.59	14.07×10^6	$0.911 L_{\odot}$
0	0	0	0	0

Fig. 7-5A The Time Variation of Some Properties of a Pre-Main-Sequence Star of Mass $1 M_{\odot}$. The abscissa is $\log t$, where t is the time in seconds measured from the initial model of the series for this mass. The upper and lower limits of each ordinate are given. The ordinates are: M_{RC}/M , the fraction of the total mass contained in a radiative core; $\log (R/R_{\odot})$, where R/R_{\odot} is the total radius relative to that of the Sun ($R_{\odot} = 6.96 \times 10^{10}$ cm); $\log (\rho_c/\bar{\rho})$, where ρ_c is the central density and $\bar{\rho}$ is the mean density; $\log T_{\text{eff}}$, where T_{eff} is the effective temperature in degrees Kelvin; and $\log (L/L_{\odot})$, where L/L_{\odot} is the luminosity relative to that of the Sun ($L_{\odot} = 3.86 \times 10^{33}$ erg sec $^{-1}$). [After I. Iben, Jr., 1965 (321).]

Fig. 7-5B The Time Variation of Some Properties of a Pre-Main-Sequence Star of Mass $1 M_{\odot}$. The abscissa is $\log t$, where t is the time in seconds measured from the initial model of the series for this mass. The upper and lower limits of the scale for each curve are given. The ordinates are M_{CC}/M , the fraction of the mass contained in a convective core; $\log \rho_c$, where ρ_c is the central density in gm cm $^{-3}$; $\log T_c$, where T_c is the central temperature in degrees Kelvin; and L_g/L , the net fraction of the luminosity that is generated by gravitational contraction (but not necessarily the fraction of the emitted radiation that is due to gravitational contraction—see text). The value of L_g/L becomes negative near $\log t = 15.0$: zero for this ordinate is on the horizontal axis. [Adapted from I. Iben, Jr., 1965 (321).]

Fig. 7-5C A Model of Mass $1 M_{\odot}$ During the Pre-Main-Sequence Phase at Time $\log t = 14.941$. The time is measured in seconds from the initial model of the series for this mass. The abscissa is the fractional mass M_r/M . The upper and lower limits of each ordinate are given. Each upper limit is the maximum value in the model. The ordinates are r , the radius in units of the solar radius ($R_{\odot} = 6.96 \times 10^{10}$ cm); P , the pressure in dyne cm $^{-2}$; ρ , the density in gm cm $^{-3}$; T , the temperature in degrees Kelvin; and L_r , the net luminosity in units of the solar luminosity ($L_{\odot} = 3.86 \times 10^{33}$ erg sec $^{-1}$). [Adapted from I. Iben, Jr., 1965 (321).]

Pre-main Sequence Evolution of a 1 M_⊙ star

$$\tau < 2 \times 10^{14} \text{ s (i.e., } 7 \times 10^6 \text{ yr)}$$

$$T_{\text{eff}} \sim \text{const} \sim 4200 \text{ K} \quad R \downarrow \Rightarrow L \downarrow$$

due to ionization of H & He
a deep convective envelope

$$\rho_c / \bar{\rho} \sim \text{const} \quad (\text{Hayashi track})$$

Star completely convective in
the first 10^6 yr

L_g/L : energy from gravitational contraction

$\tau \sim 14.5$, $L \uparrow$ \Rightarrow nuclear reactions
(10^7 yr)

(cont.)

~ 15

\Rightarrow expanding the core

$\rho_c \downarrow$, $T_c \downarrow$

But T_c not high enough

only ${}^1\text{H} \rightarrow {}^2\text{D} \rightarrow {}^3\text{He}$

${}^{12}\text{C} \rightarrow {}^{13}\text{N} \rightarrow {}^{13}\text{C} \rightarrow {}^{14}\text{N}$

The rest of PP chains or CNO cycle do not operate yet

Note $L_{\text{nuc}} + L_g \equiv L$

$\tau \sim 15$, $L_g < 0$ (\because core expansion)

$$\epsilon_{\text{nuc}} \uparrow \rightarrow \nabla T \uparrow$$

\Rightarrow A temporary convective core ($\tau \sim 14.9$)
until ^{12}C is depleted and
pp chains become important

Eventually $\nabla T \downarrow$ at core, convective core \downarrow
($\tau \sim 15.3$)

$\tau \sim 15$, $L \rightarrow L_{\text{max}}$

Structure of star adjusts

∴ Energy sources from gravitational
to nuclear processes

$\therefore T_c, P_c$ never high enough to ignite ^{12}C

Fig. 7-3B Evolutionary Tracks of Pre-Main-Sequence Stars of Low Mass in the Hertzsprung-Russell Diagram. The masses, and the ages at two points on each track, are indicated. The heavy curve (MS) is the hydrogen-burning main sequence. The convective parameter is assumed to have the value $l/H = 1.0$. [Adapted from A. S. Grossman and H. C. Graboske, Jr., 1971 (400).]

Effect of Stellar Rotation

Fig. 1. The decrease of the luminosity with increasing rotation measured by Ω^2/Ω_{\max}^2 , where Ω refers to the angular velocity of rotation and the subscript max to the critical case. The Arabic numeral refers to the mass of each sequence in solar units

$$\frac{\Omega}{\Omega_{\text{crit}}} \nearrow \rightarrow L \searrow$$

More so for lower-mass stars

Rotation effectively lowers the stellar mass.

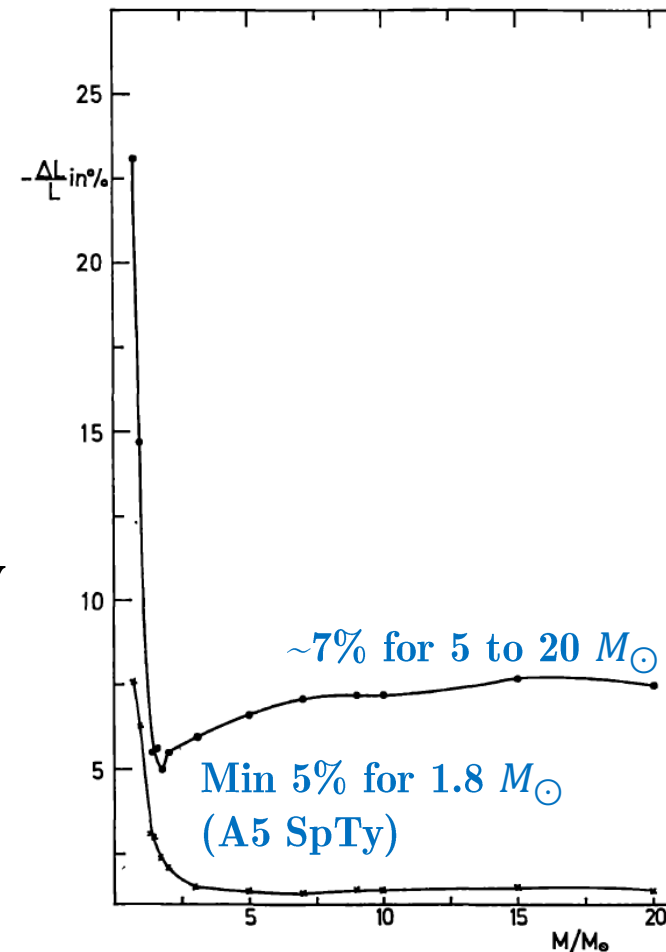

Fig. 5. The maximum change in the luminosity of a critically rotating star from that of a non-rotating star of the same mass, expressed in percent, against the mass of the main-sequence model. The dots refer to the actual results of the Stellar Interior models, while the crosses refer to the approximations made for Eq. (12)

Rotation → star cooler and fainter

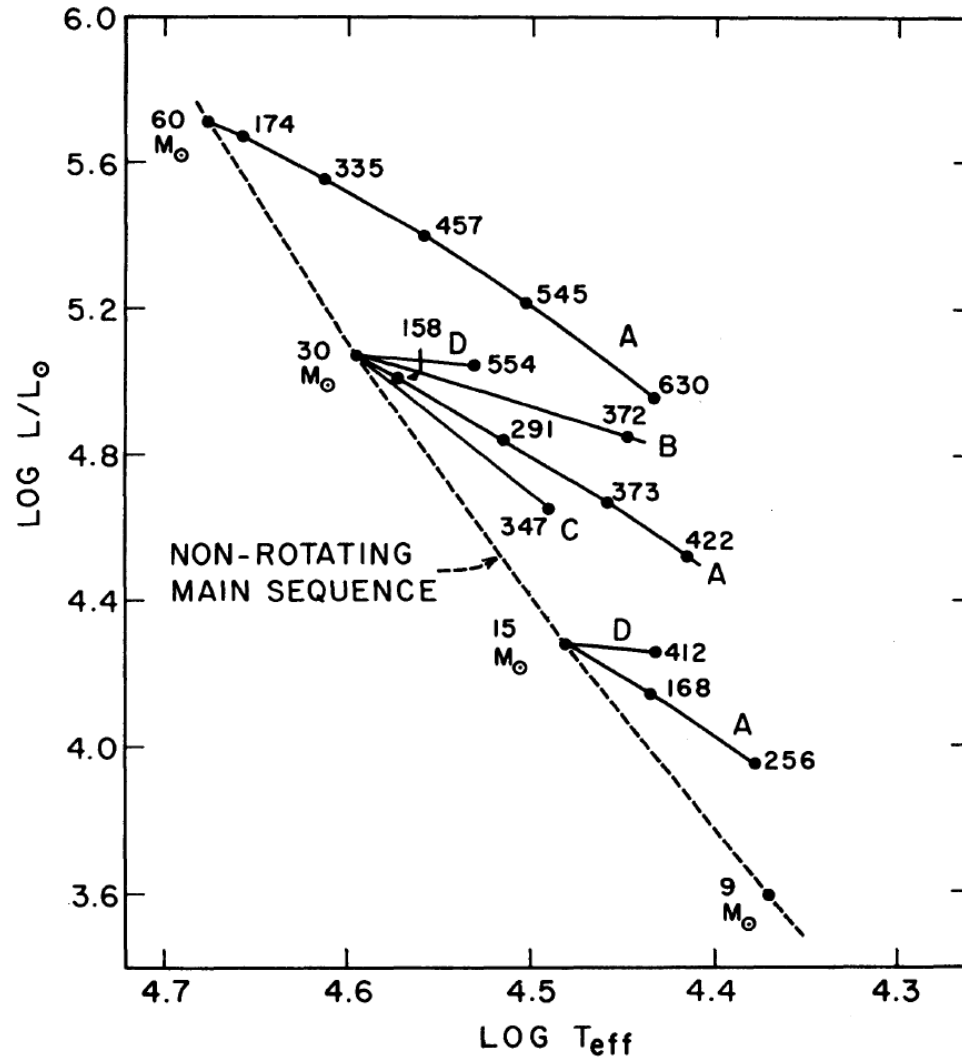

FIG. 2.—Theoretical H-R diagram showing model sequences of increasing angular momentum (*solid curves*). Numbers on curves give calculated velocities at the equator in km sec^{-1} . The distribution of angular momentum for each sequence is indicated by the letter A, B, C, or D.

FIG. 1.—Angular momentum per unit mass, as a function of mass fraction interior to a given cylinder about the axis of rotation, for three assumed laws of differential rotation (Cases A, B, and C) and for a uniformly rotating model (Case D) of $30 M_{\odot}$, $\log J = 52.73$.

D: solid body rotation

Rotation law:

angular momentum distribution
 $j(m_w)$ as a function of, m_w , the mass fraction interior to the cylinder of radius w about the rotation axis.

Rotation → line broadening

Fig. 17.7. (a) Computed profiles illustrate the broadening effect of rotation. The profiles are labeled with $v \sin i$. the wavelength is 4243 Å, and the line has an equivalent width of 100 mÅ. (b) These two early-G giants illustrate the Doppler broadening of the line profiles by rotation.

Rotation vs Spectral Type

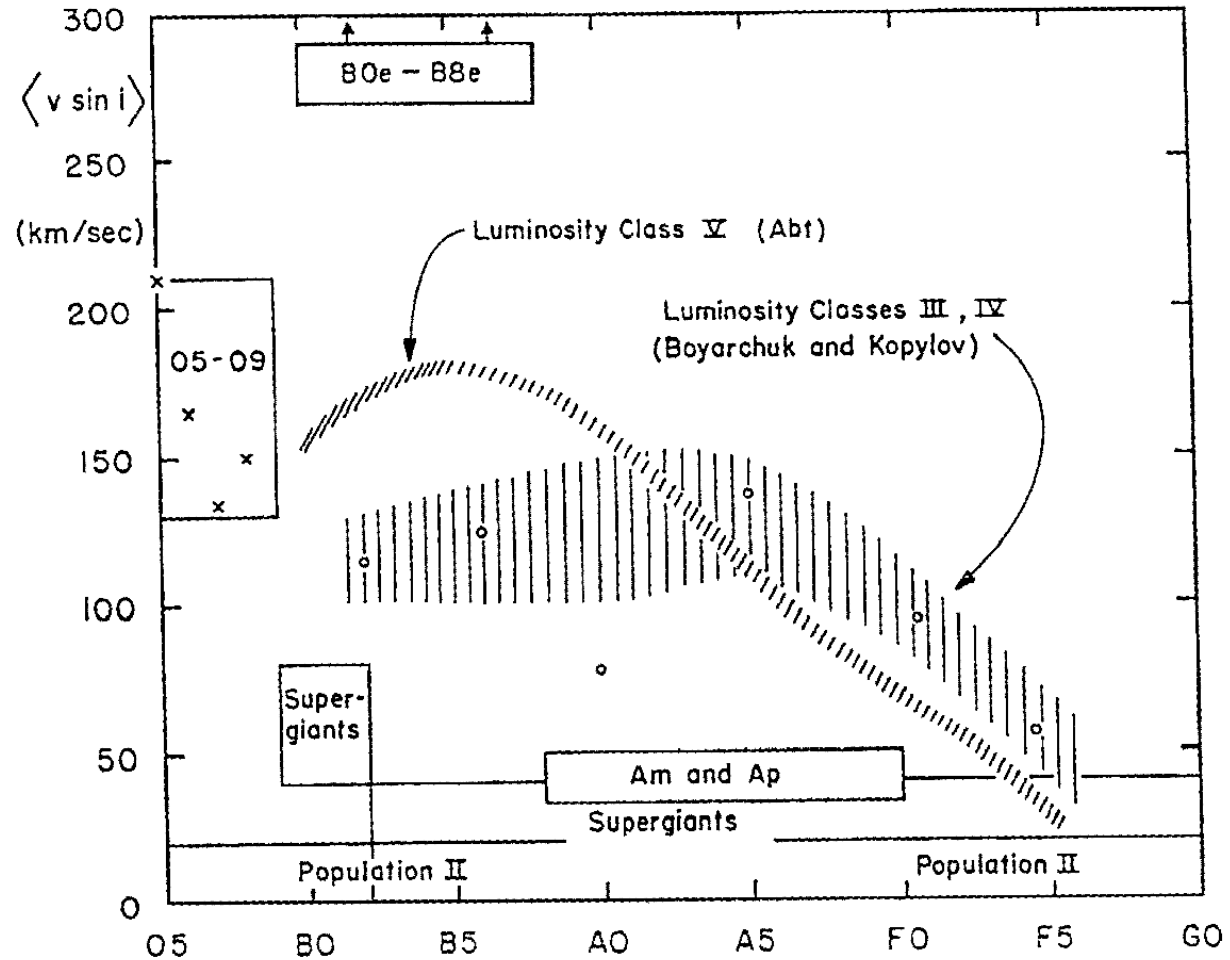

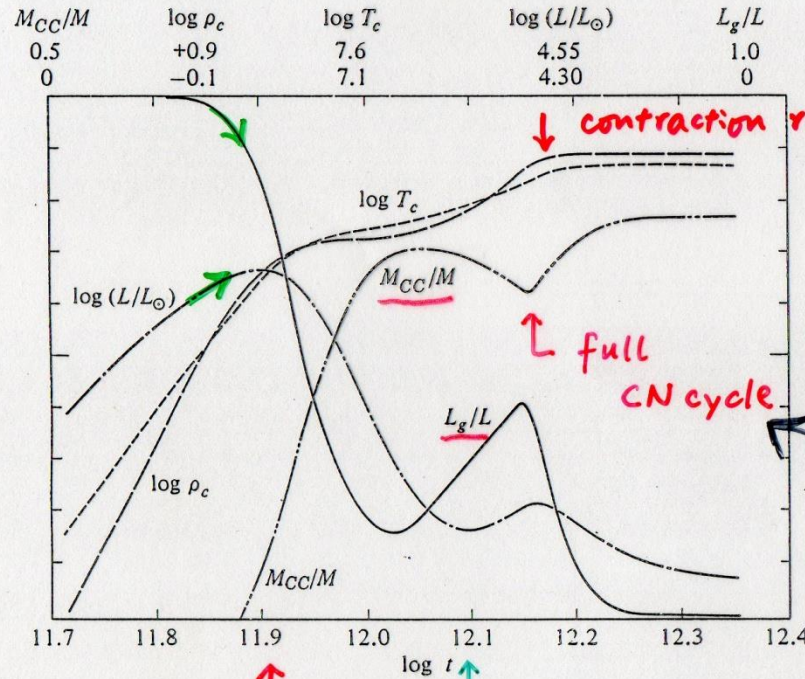

Fig. 3. Projected equatorial velocities, averaged over all possible inclinations, as a function of spectral type. On the main sequence (luminosity class V), early-type stars have rotational velocities that reach and even exceed 200 km/s; these velocities drop to a few km/s for late-type stars, such as the Sun (type G2) (Slettebak [20]; courtesy Gordon & Breach)

15 M_{\odot}

* A number in parentheses is the power of 10 by which an entry is to be multiplied.

Fig. 7-25 Evolutionary Tracks in the Hertzsprung-Russell Diagram. The mass of each star is given at the left of the track. The composition is $X = 0.708$, $Y = 0.272$, and $Z = 0.020$ for all masses except $30 M_{\odot}$, for which the composition is $X = 0.70$, $Y = 0.27$, $Z = 0.03$. Dashed portions of the curves are estimates. The letters along the tracks for $1 M_{\odot}$ and $5 M_{\odot}$ have the following significance: H_c = hydrogen-burning near the center; G = gravitational contraction of the entire star; H_{TS} = hydrogen-burning in a thick shell; H_s = hydrogen-burning in a thin shell; He = helium-burning near the center plus hydrogen-burning in a thin shell. The times required to reach the encircled points are given in Table 7-7.

The dotted lines indicate the boundaries of the main sequence. The line (lower left) shows the slope of a path along which the radius remains constant. The track for $15 M_{\odot}$ does not turn back as do the other tracks because the semi-convective zone was treated as fully convective [see R. Stothers and C.-W. Chin, 1968 (377)]. [Adapted from I. Iben, Jr., 1967 (327). The track for $30 M_{\odot}$ is given by R. Stothers, 1966 (333).]

ON THE EVOLUTION OF THE MAIN-SEQUENCE STARS

M. SCHÖNBERG¹ AND S. CHANDRASEKHAR

ABSTRACT

The evolution of the stars on the main sequence consequent to the gradual burning of the hydrogen in the central regions is examined. It is shown that, as a result of the decrease in the hydrogen content in these regions, the convective core (normally present in a star) eventually gives place to an isothermal core. It is further shown that there is an upper limit (~ 10 per cent) to the fraction of the total mass of hydrogen which can thus be exhausted. Some further remarks on what is to be expected beyond this point are also made.

$$\frac{M_c}{M} \approx 0.37 \left(\frac{\mu_e}{\mu_c} \right)^2 \left(\sim 10-15\% \text{ in reality} \right)$$

Present Sun

Fig. 7-11A A Model Solar Interior. Density relative to the central density ρ/ρ_c , temperature relative to central temperature T/T_c , net luminosity relative to total luminosity L_r/L_\odot , and hydrogen abundance X are shown as functions of fractional mass M_r/M . The chemical composition is $X = 0.730$, $Y = 0.245$, and $Z = 0.025$. The age is 4.5×10^9 years. [After S. Torres-Peimbert, E. Simpson, and R. K. Ulrich, 1969 (329).]

$X_c = 0.376$

Sun on the main sequence

Fig. 7-11B The Evolution of the Sun during 7 Billion Years. Total luminosity L and central values of pressure P_c , temperature T_c , density ρ_c , and hydrogen abundance X_c are shown as functions of time t , which is measured from the initial (homogeneous) state for which the composition is $X = 0.730$, $Y = 0.245$, and $Z = 0.025$. The power of ten by which each value must be multiplied is indicated in parentheses. The values of P_c , ρ_c , and L are expressed in cgs units, and T_c is expressed in degrees Kelvin. [After S. Torres-Peimbert, E. Simpson, and R. K. Ulrich, 1969 (329).]

$P_{deg} \sim 0.017 P_{total}$ at ZAMS

0.075

9.2×10^9 yr

(Fig 7-10B)

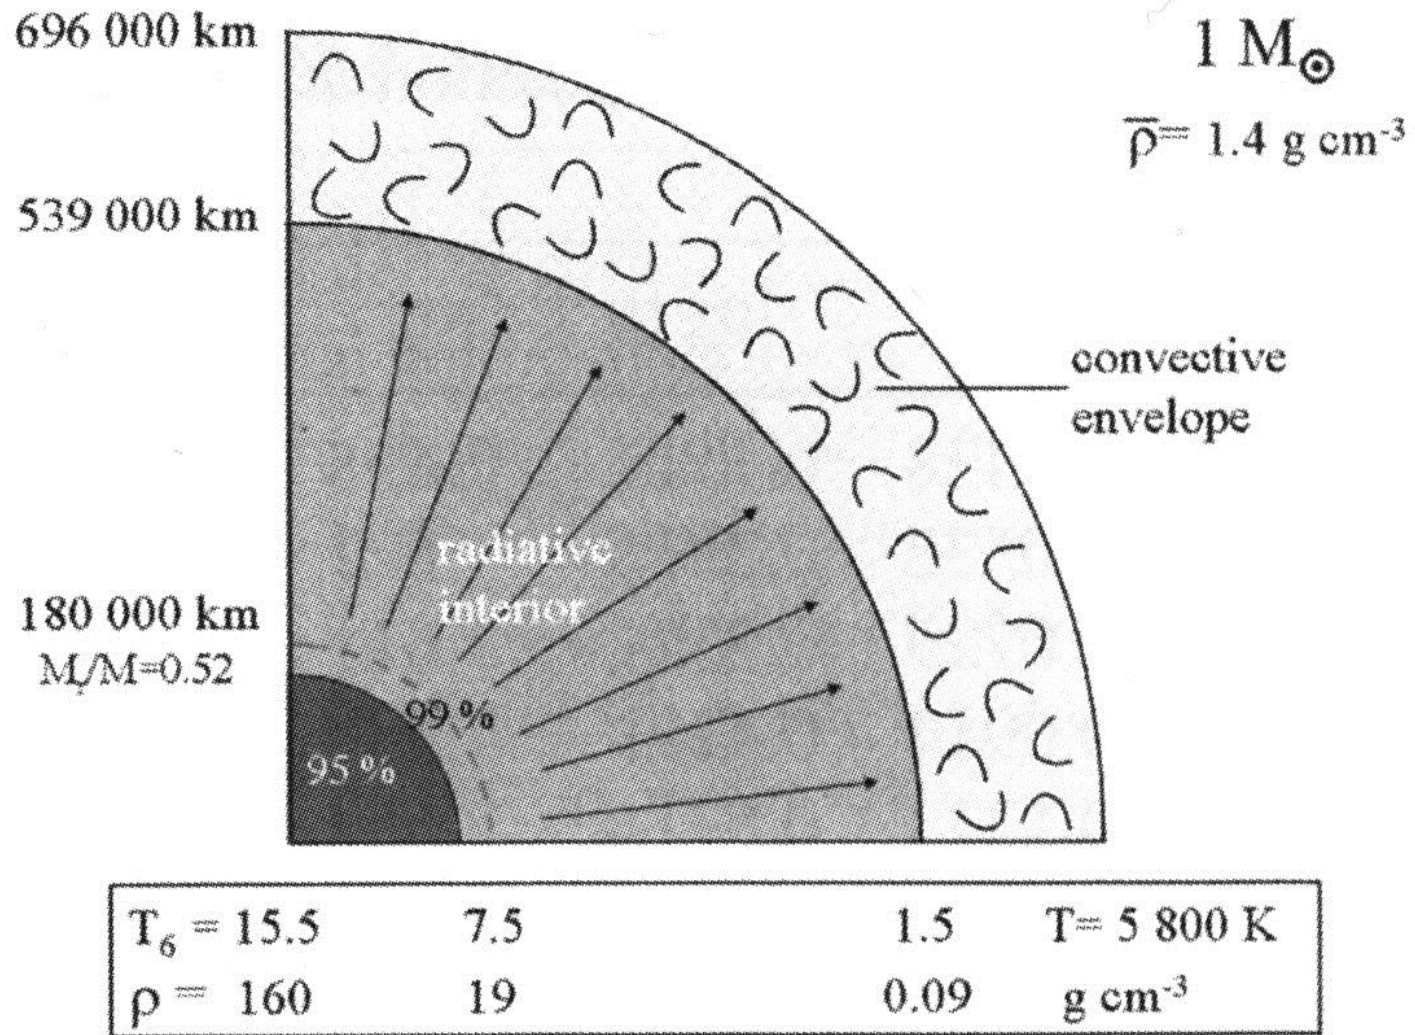

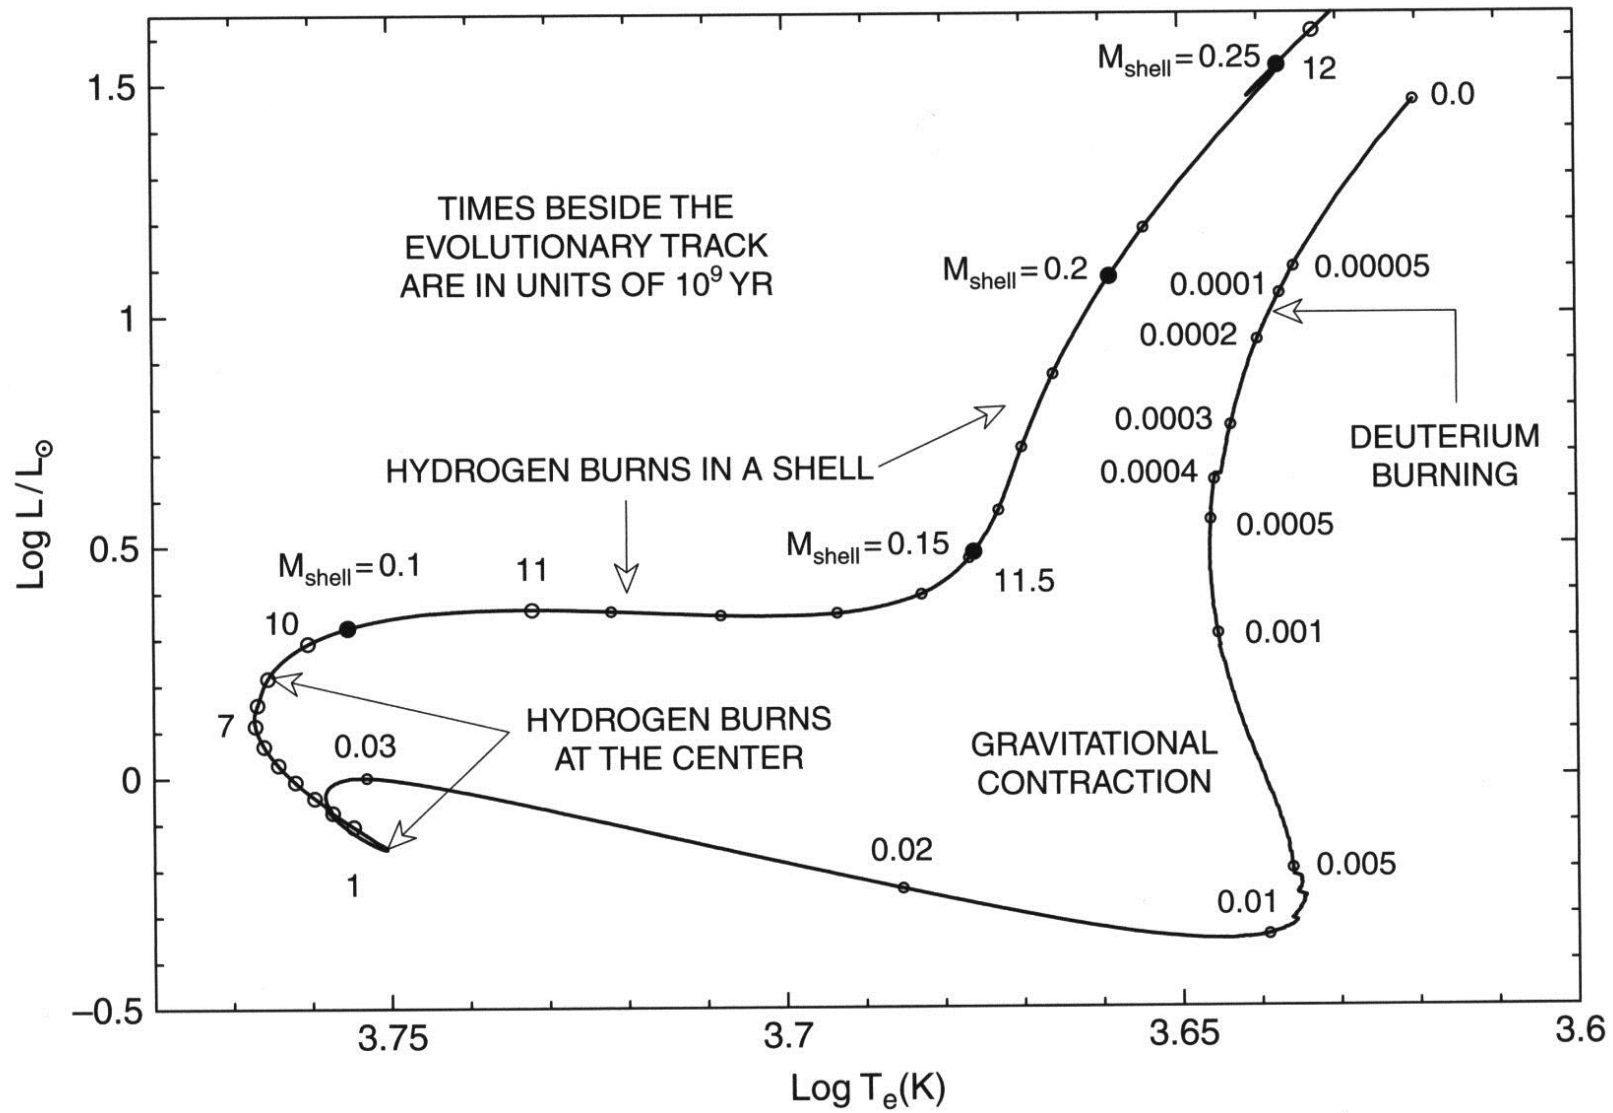

Figure 3.2. The present structure of the Sun. The physical parameters are indicated in the figure. The temperature T_6 is in million K. *From Maeder (2009).*

Evolutionary track of a $1M_{\odot}$ model ($Z = 0.015, Y = 0.275$) during gravitational contraction and central and shell hydrogen-burning phases

Figure 3.1. The evolution of the Sun. The evolution track of a solar-mass star is shown in the HR diagram from its formation to its death as a planetary nebula. Time is indicated at different steps along the track. The two 4-branch stars correspond to the helium flash and to the subsequent rapid rearrangement of the structure of the star. *From Maeder (2009), data from Corinne Charbonnel.*

Effect of Chemical Composition

As $X \uparrow$ or $Z \uparrow$
 \Rightarrow MS shifts upwards
 Given a mass,
 shifted to the right
 and downwards

Fig. 7-15A The Effect of Chemical Composition on the Main Sequence in the Hertzsprung-Russell Diagram. Each curve is calculated for a different chemical composition. The masses $0.6 M_{\odot}$, $0.8 M_{\odot}$, and $1.0 M_{\odot}$ are indicated. [From P. Demarque, 1960 (369).]

For Pop I $\left(\begin{array}{l} 0.57 \lesssim X \lesssim 0.77 \\ 0.01 \lesssim Z \lesssim 0.03 \end{array} \right) \quad \Delta M_{bol} \sim 0.8 \text{ mag for } 1 M_{\odot}$

Pop II similar range in ΔM_{bol}

Main Sequence Phase = core H burning

Evidence of thermonuclear reactions at a star's center, i.e., stellar evolution

- (solar) neutrinos

- heavy elements in evolved stars

(isotope ratios \neq YSOs)

'dredge-up' \leftarrow convective zone

to bring processed materials to surface

- Stars "disappear", e.g., supernovae

$M \uparrow \Rightarrow$ smaller outer convective zone

For the Sun, convective zone only 2% solar mass below the photosphere

$M \lesssim 0.3 M_{\odot}$
star fully convective

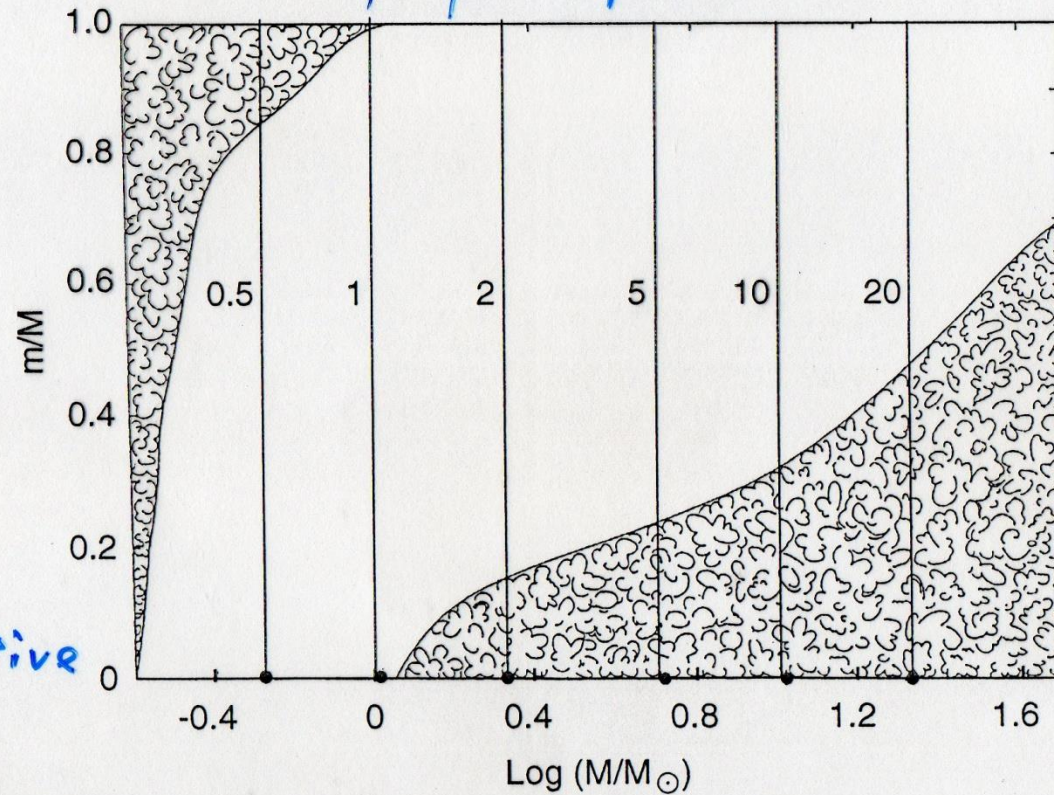

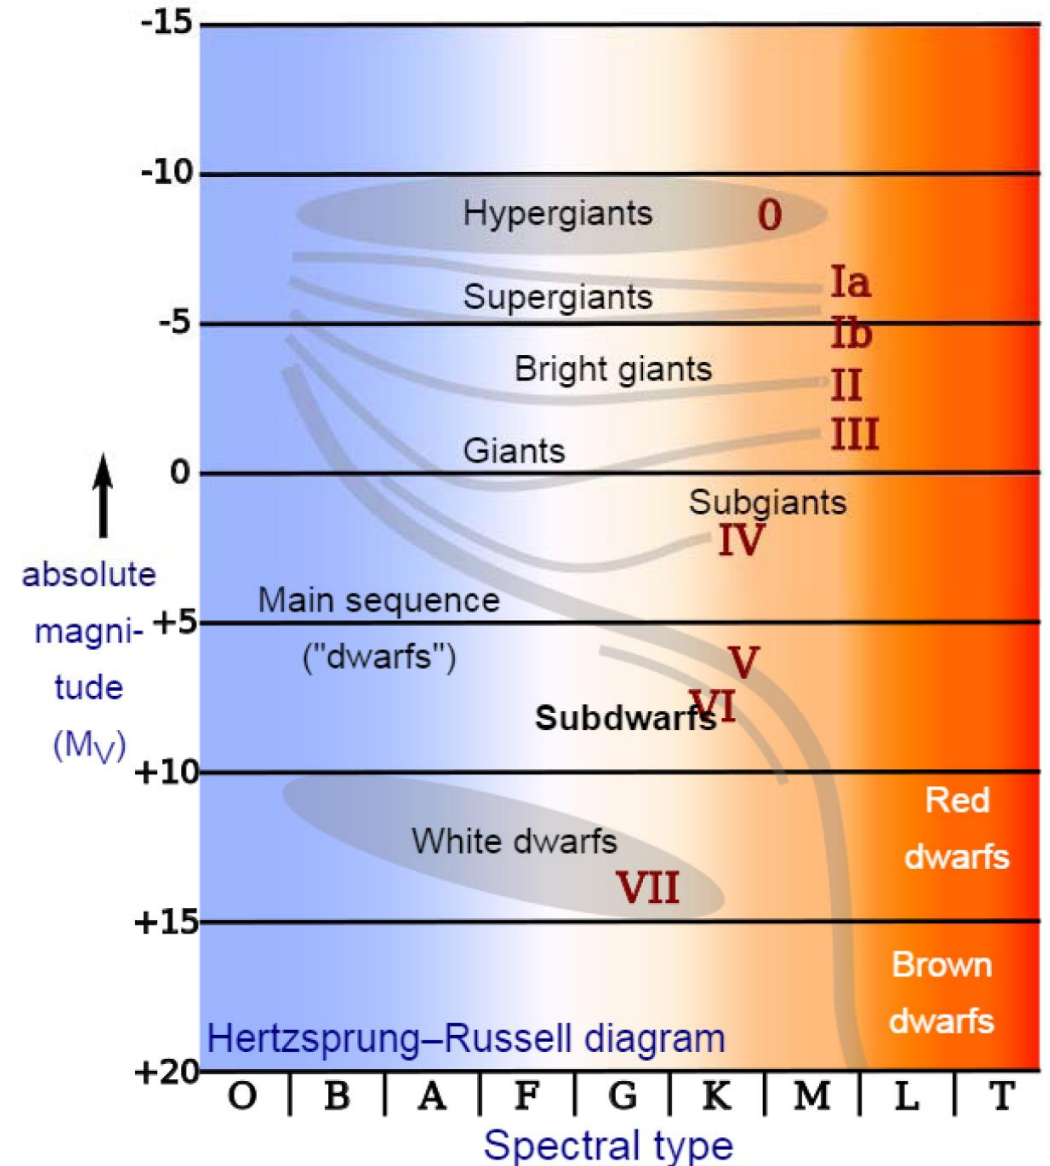

Figure 8.4 The extent of convective zones (shaded areas) in main-sequence star models as a function of the stellar mass [adapted from R. Kippenhahn & A. Weigert (1990), *Stellar Structure and Evolution*, Springer-Verlag].

Subdwarfs: The Pop II Main Sequence

- ◆ Luminosity class VI
- ◆ 1.5 to 2 mag fainter than a Pop I MS stars of the same spectral type
- ◆ Low metallicity \rightarrow low opacity \rightarrow (UV excess) \rightarrow low radiation pressure, so smaller, hotter for the same stellar mass

Fig. 17.1. Relation of subdwarfs to the main-sequence in the Hertzsprung-Russell diagram.
