"Introduction to Stellar Atmospheres and Interiors" by Eva Novotny

STELLAR EVOLUTION. I. THE APPROACH TO THE MAIN SEQUENCE*

ICKO IBEN, JR.
California Institute of Technology, Pasadena, California
Received August 18, 1964; revised November 23, 1964

ABSTRACT

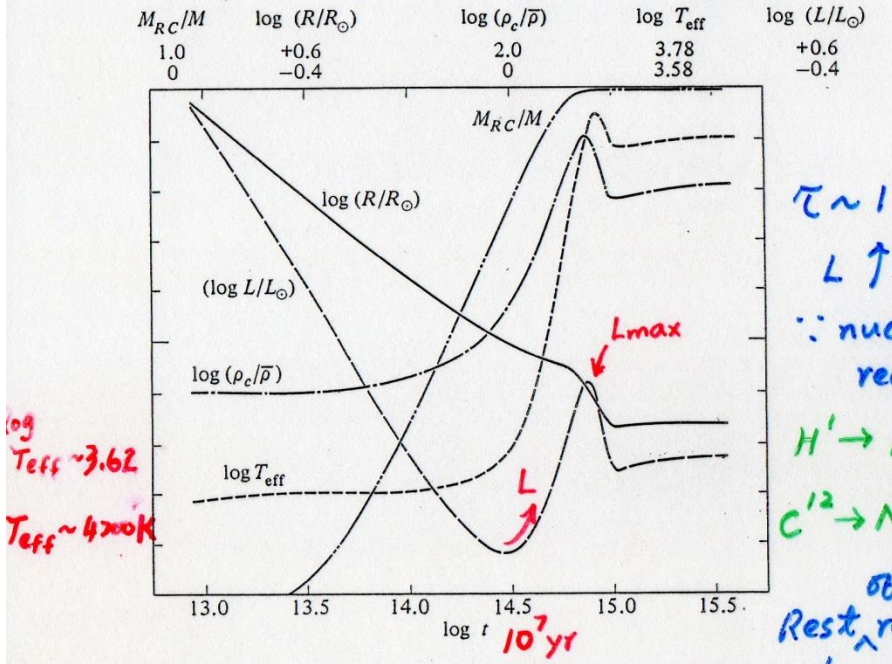
The manner in which nuclear reactions replace gravitational contraction as the major source of stellar luminosity is investigated for model stars of population I composition in the mass range $0.5 < M/M_{\odot} < 15$ 0. By following in detail the depletion of C^{12} from high initial values down to values corresponding to equilibrium with N^{14} in the C-N cycle, the approach to the main sequence in the Hertzsprung-Russell diagram and the time to reach the main sequence, for stars with $M \geq 1.25\ M_{\odot}$, are found to differ significantly from data reported previously.

PMS

$1\ M_\odot$

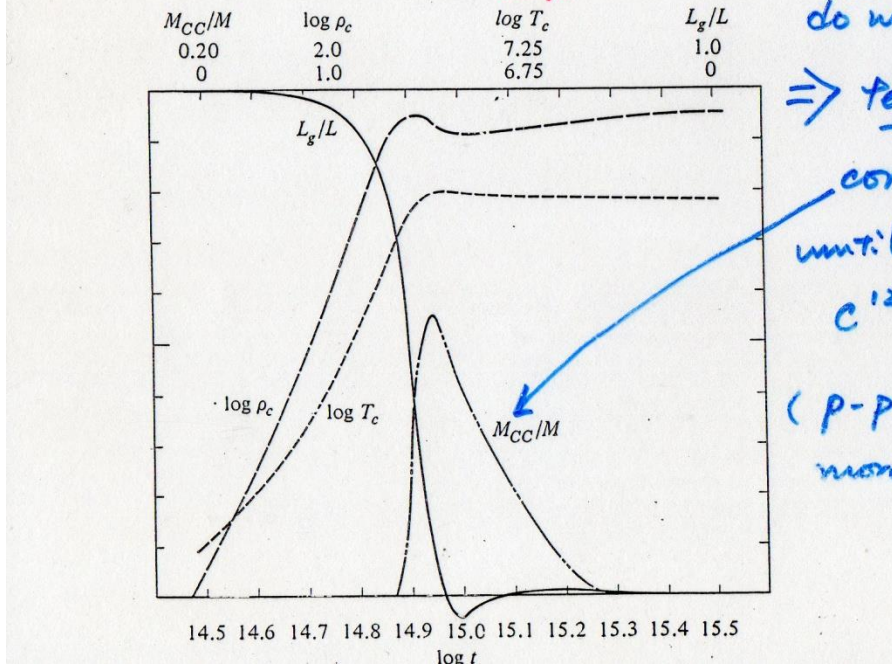
$L \equiv L_{nuc} + L_{grav}$

$L_{nuc} = \int_0^M \epsilon\, dM_r$



log T_{eff} ~3.62

T_{eff} ~ 4200K



$\tau \sim 14.5$

$L \uparrow$

∵ nuclear reactions

$H^1 \rightarrow H^2 \rightarrow He^3$

$C^{12} \rightarrow N^{13} \rightarrow C^{13}$

$\rightarrow N^{14}$

& Rest reactions do not operate

$\Rightarrow$ temporary convective core until C^{12} depleted

(p-p chain more important)

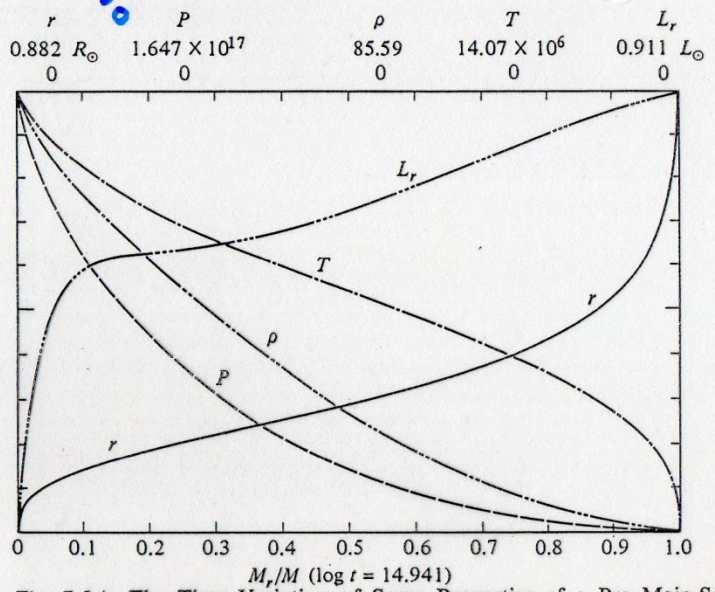


Fig. 7-5A The Time Variation of Some Properties of a Pre–Main-Sequence Star of Mass 1 $M_\odot$. The abscissa is log t, where t is the time in seconds measured from the initial model of the series for this mass. The upper and lower limits of each ordinate are given. The ordinates are: M_{RC}/M, the fraction of the total mass contained in a radiative core; log $(R/R_\odot)$, where $R/R_\odot$ is the total radius relative to that of the Sun ($R_\odot = 6.96 \times 10^{10}$ cm); log $(\rho_c/\bar{\rho})$, where ρ_c is the central density and $\bar{\rho}$ is the mean density; log T_{eff}, where T_{eff} is the effective temperature in degrees Kelvin; and log $(L/L_\odot)$, where $L/L_\odot$ is the luminosity relative to that of the Sun ($L_\odot = 3.86 \times 10^{33}$ erg sec^{-1}). [After I. Iben, Jr., 1965 (321).]

Fig. 7-5B The Time Variation of Some Properties of a Pre–Main-Sequence Star of Mass 1 $M_\odot$. The abscissa is log t, where t is the time in seconds measured from the initial model of the series for this mass. The upper and lower limits of the scale for each curve are given. The ordinates are M_{CC}/M, the fraction of the mass contained in a convective core; log ρ_c, where ρ_c is the central density in gm cm^{-3}; log T_c, where T_c is the central temperature in degrees Kelvin; and L_g/L, the net fraction of the luminosity that is generated by gravitational contraction (but not necessarily the fraction of the *emitted* radiation that is due to gravitational contraction—see text). The value of L_g/L becomes negative near log t = 15.0: zero for this ordinate is on the horizontal axis. [Adapted from I. Iben, Jr., 1965 (321).]

Fig. 7-5C A Model of Mass 1 $M_\odot$ During the Pre–Main-Sequence Phase at Time log t = 14.941. The time is measured in seconds from the initial model of the series for this mass. The abscissa is the fractional mass M_r/M. The upper and lower limits of each ordinate are given. Each upper limit is the maximum value in the model. The ordinates are r, the radius in units of the solar radius ($R_\odot = 6.96 \times 10^{10}$ cm); P, the pressure in dyne cm^{-2}; ρ, the density in gm cm^{-3}; T, the temperature in degrees Kelvin; and L_r, the net luminosity in units of the solar luminosity ($L_\odot = 3.86 \times 10^{33}$ erg sec^{-1}). [Adapted from I. Iben, Jr., 1965 (321).]

Pre-main Sequence Evolution of a $1\,M_\odot$ Star

$\tau < 2 \times 10^{14}$ s (i.e. 7×10^6 yr)

$T_{eff} \sim$ const $\sim$ 4200 K $R \downarrow \Rightarrow L \downarrow$

due to ionization of H & He
a deep convective envelope

$\rho_c / \bar{\rho} \sim$ const (Hayashi track)

Star completely convective in the first 10^6 yr

L_g / L : energy from gravitational contraction

$\tau \sim 14.5$, $L \uparrow \Rightarrow$ **nuclear reactions**

$(10^7 yr)$

(cont.)

~ 15

$\Rightarrow$ expanding the core

$P_c \downarrow$, $T_c \downarrow$

But T_c not high enough

only $^1H \rightarrow {}^2D \rightarrow {}^3He$

$^{12}C \rightarrow {}^{13}N \rightarrow {}^{13}C \rightarrow {}^{14}N$

The rest of PP chains or CNO cycle do not operate yet

Note $L_{nuc} + L_g \equiv L$

$\tau \sim 15$, $L_g < 0$ ($\because$ core expansion)

$\epsilon_{nuc} \uparrow \rightarrow \nabla T \uparrow$

$\Rightarrow$ A temporary convective core ($\tau \sim 14.9$)

until ^{12}C is depleted and

pp chains become important

Eventually $\nabla T \downarrow$ at core, convective core $\downarrow$

($\hat{\tau} \sim 15.3$)

$\tau \sim 15$, $L \rightarrow L_{max}$

Structure of star adjusts

∵ Energy sources from gravitational

to nuclear processes

⇒ ^{12}C main sequence ! Point 5

short lasting, depletion rapidly

→ slight contraction

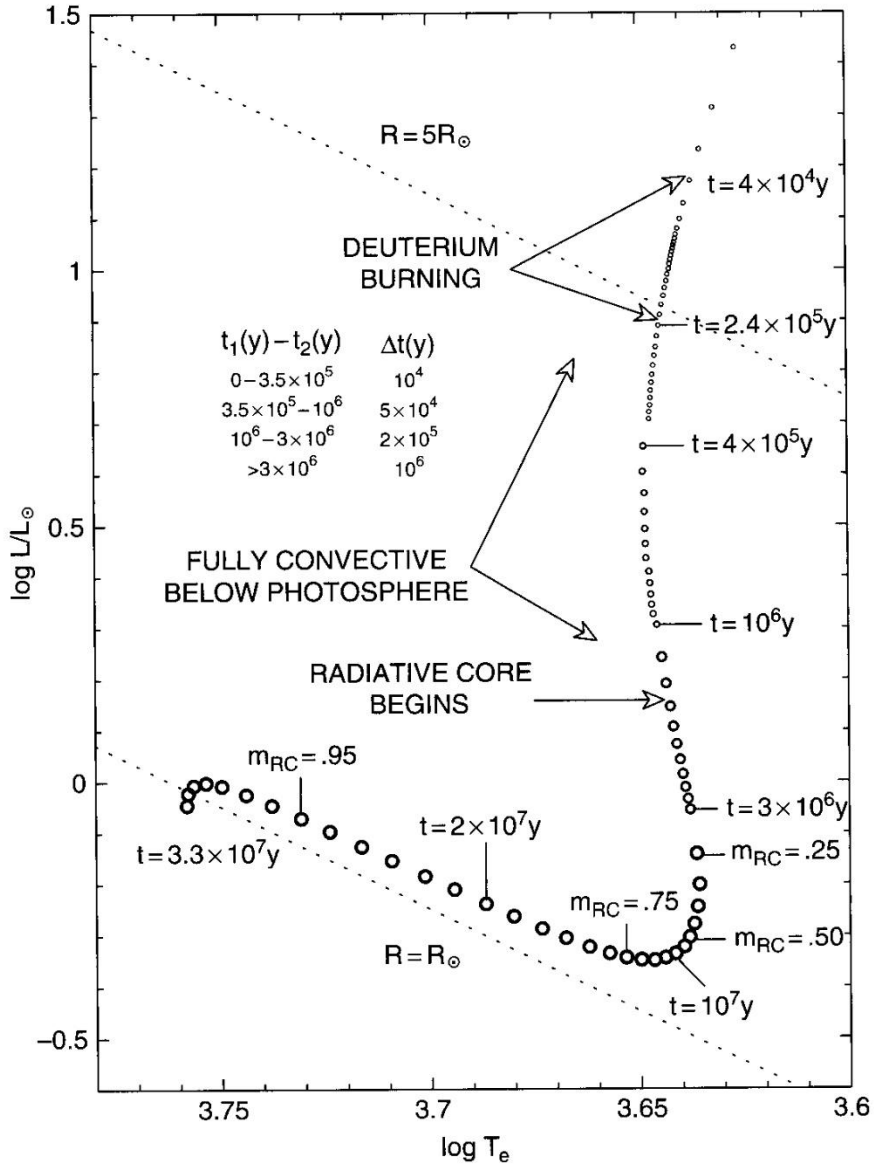
T_c, ρ_c high enough for PP reactions

to be the sole energy source.

For all Stars $M \gtrsim M_\odot \Rightarrow$ convective core

^{12}C burning $\longrightarrow$ recedes

For Stars $M \gtrsim 1.25\, M_\odot \Rightarrow$ double luminosity maxima and minima



Pre main sequence evolution in the HR diagram of a low mass model ($M = 1M_{\odot}, Z = 0.01, Y = 0.25$)

Iben 2013

For $0.5\ M_\odot$ stars,

ρ_c, T_c not high enough for ^{12}C burning

For $M \lesssim 0.1\ M_\odot$ (dependent on μ)

T_c not high enough for even H burning

$\Rightarrow$ contraction continues

$\rightarrow$ degenerate core

$\Rightarrow$ black dwarfs ... nowadays called brown dwarfs

only the initial, nearly vertical descent

∴ T_c, ρ_c never high enough to ignite ^{12}C

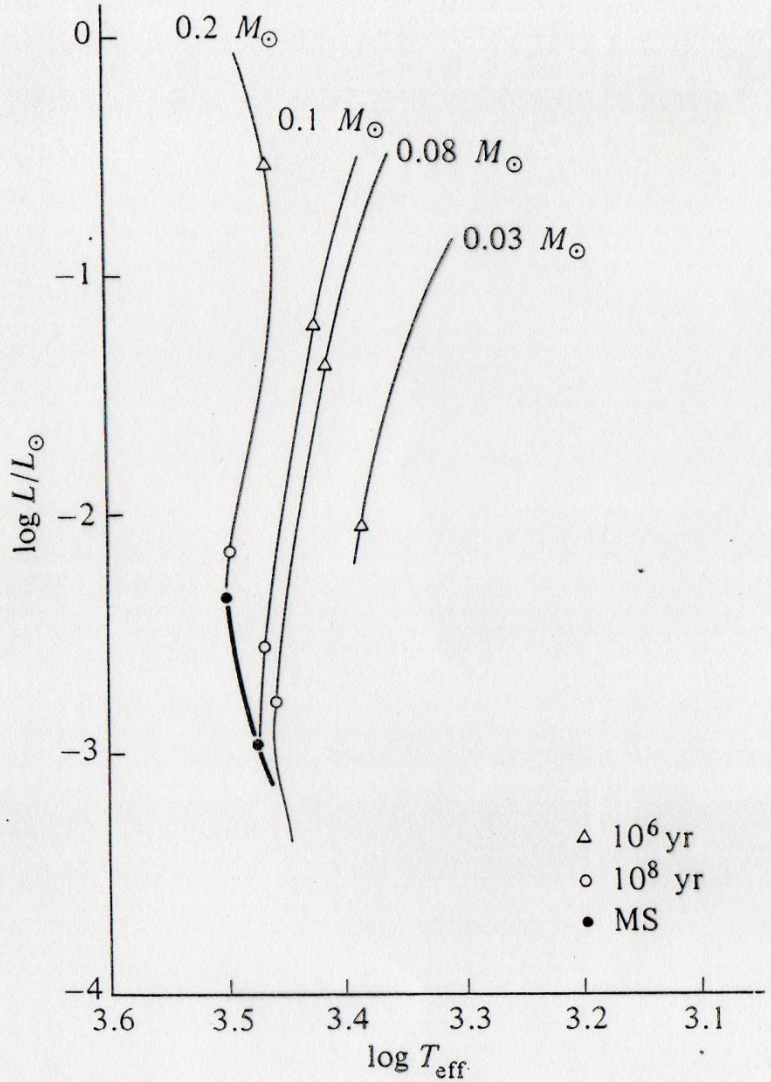


Fig. 7-3B Evolutionary Tracks of Pre–Main-Sequence Stars of Low Mass in the Hertzsprung–Russell Diagram. The masses, and the ages at two points on each track, are indicated. The heavy curve (*MS*) is the hydrogen-burning main sequence. The convective parameter is assumed to have the value $l/H = 1.0$. [Adapted from A. S. Grossman and H. C. Graboske, Jr., 1971 (400).]

Rotation → star cooler and fainter

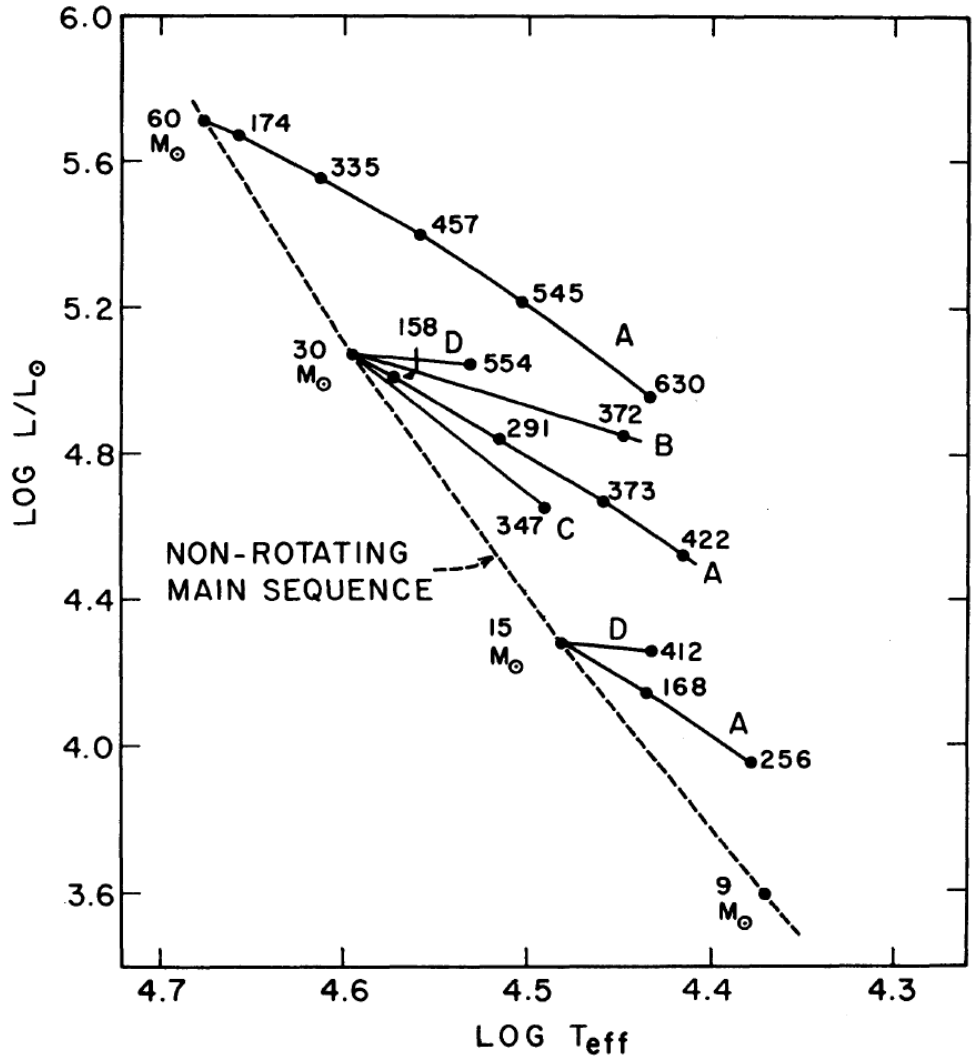

FIG. 2.—Theoretical H-R diagram showing model sequences of increasing angular momentum (*solid curves*). Numbers on curves give calculated velocities at the equator in km sec^{-1}. The distribution of angular momentum for each sequence is indicated by the letter A, B, C, or D.

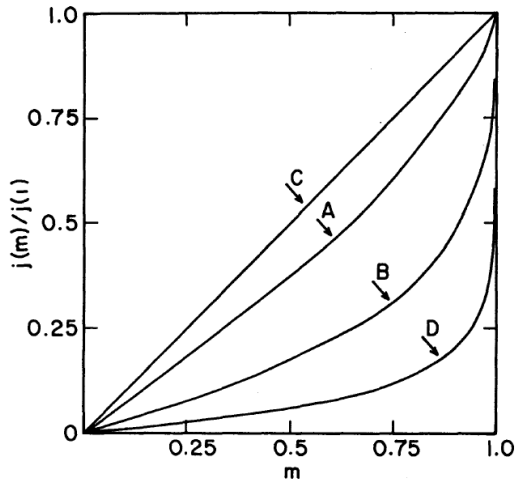

FIG. 1.—Angular momentum per unit mass, as a function of mass fraction interior to a given cylinder about the axis of rotation, for three assumed laws of differential rotation (Cases A, B, and C) and for a uniformly rotating model (Case D) of 30 $\mathfrak{M}_\odot$, log J = 52.73.

D: solid body rotation

Rotation law:

G1 IIIe

HR 3664 G6 III

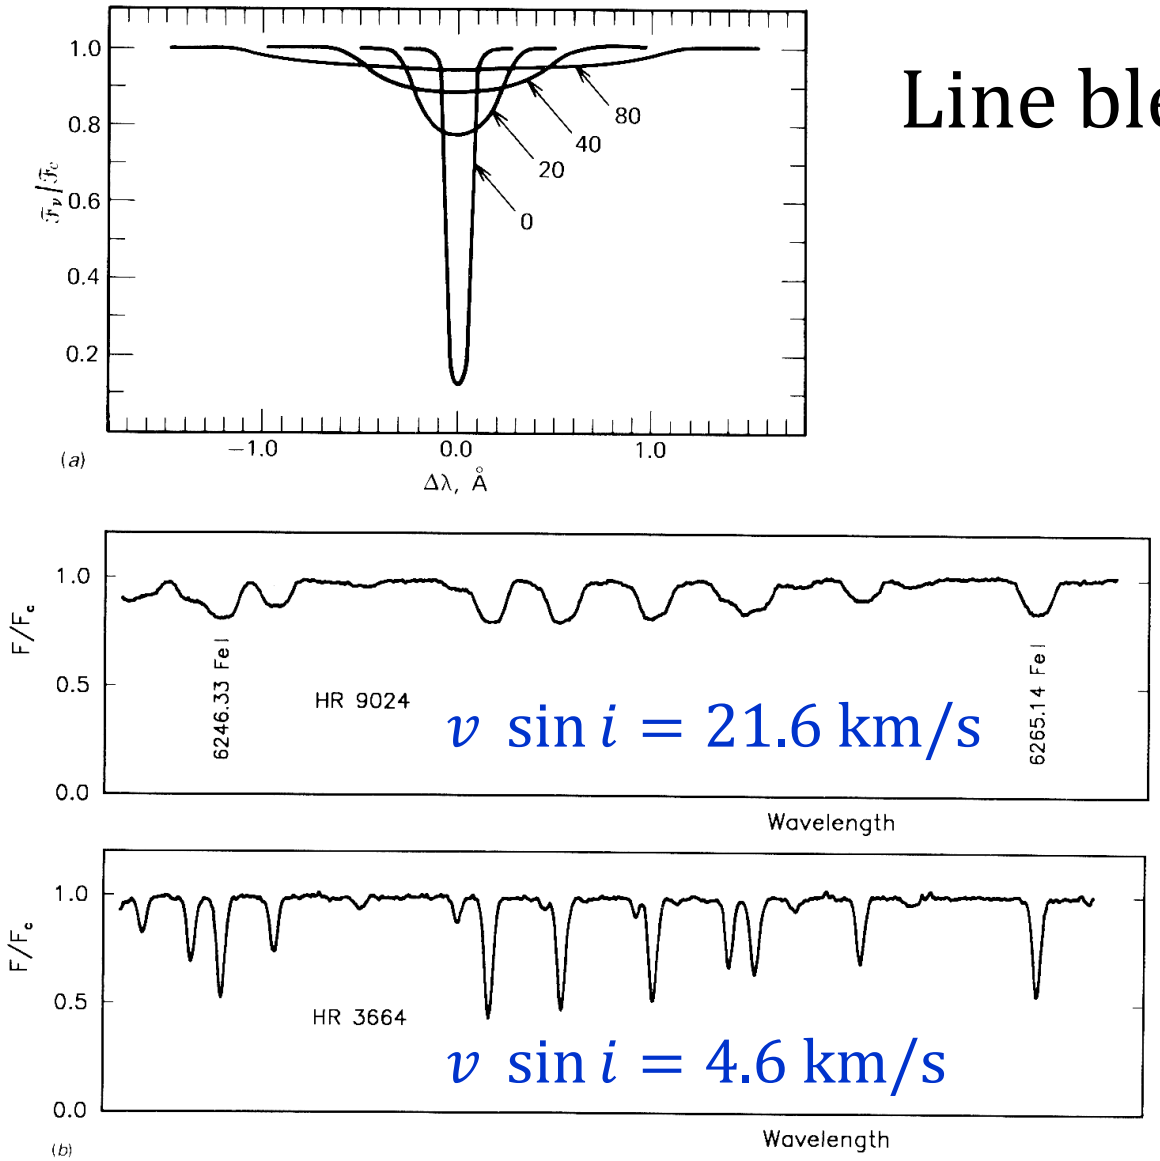

Fig. 17.7. (*a*) Computed profiles illustrate the broadening effect of rotation. The profiles are labeled with $v \sin i$. the wavelength is 4243 Å, and the line has an equivalent width of 100 mÅ. (*b*) These two early-G giants illustrate the Doppler broadening of the line profiles by rotation.

Gray p. 376

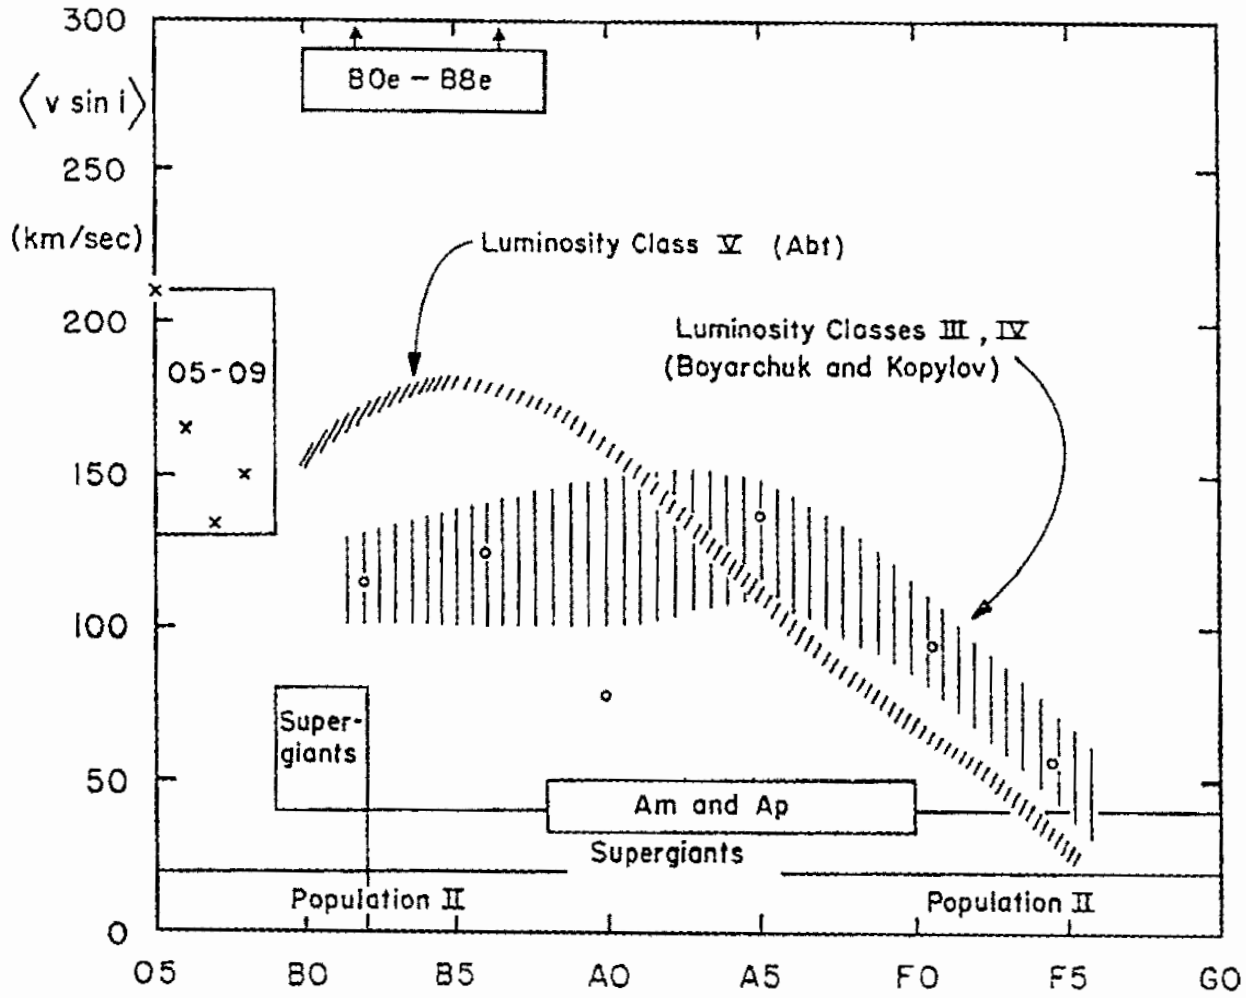

Fig. 3. Projected equatorial velocities, averaged over all possible inclinations, as a function of spectral type. On the main sequence (luminosity class V), early-type stars have rotational velocities that reach and even exceed 200 km/s; these velocities drop to a few km/s for late-type stars, such as the Sun (type G2) (Slettebak [20]; courtesy Gordon & Breach)

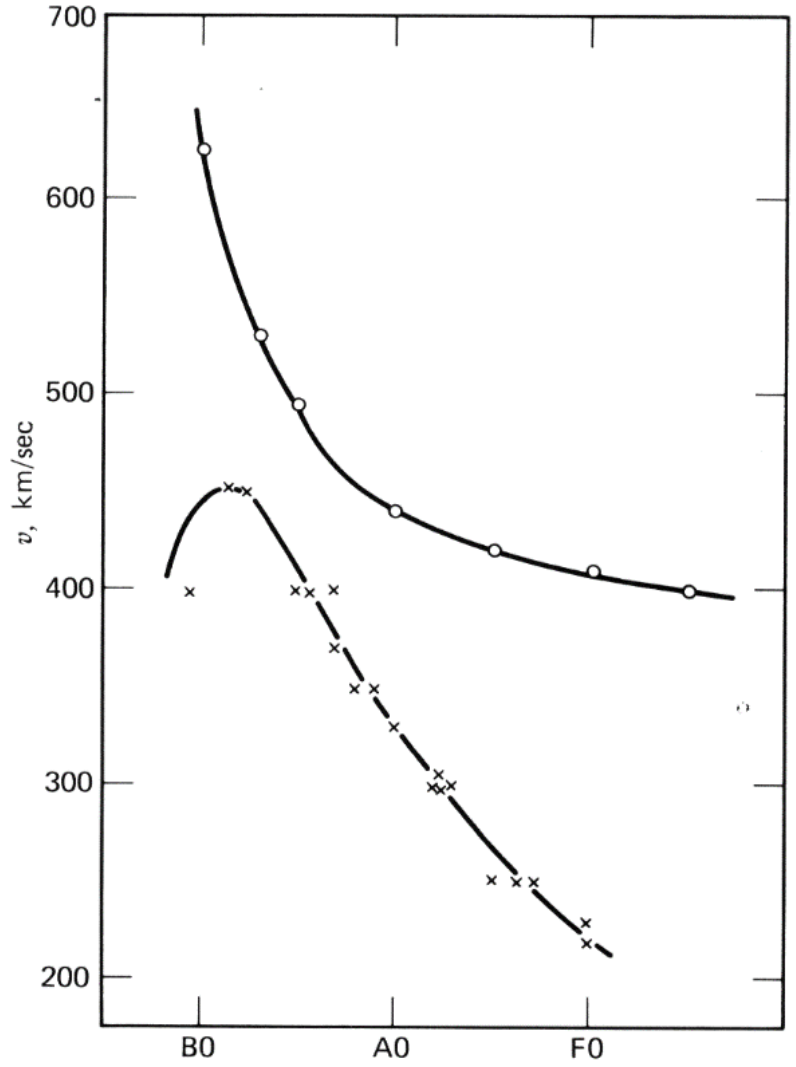

Fig. 17.22. The fastest rotation rates are shown by the × s. The theoretical break-up velocities (top curve) approach the observed relation most closely in the B-star range. (Data from Slettebak (1966).)

- ✓ The fastest <u>single</u> rotators, other than remnant objects such as neutron stars, are Be stars.
- ✓ As fast as ~450 km/s, close to break-up speed
- ✓ Mass loss preferentially along the equators.
- ✓ Stars no longer spherical

Rotation vs Spectral Type

- ✓ Massive stars are fast rotators.
- ✓ Rotation declines in the F type (convection? disk?)
- ✓ Low-mass stars spin down quickly early on (disk-star coupling of **B** field), and then experience weak-breaking on the MS due to magnetic breaking and winds

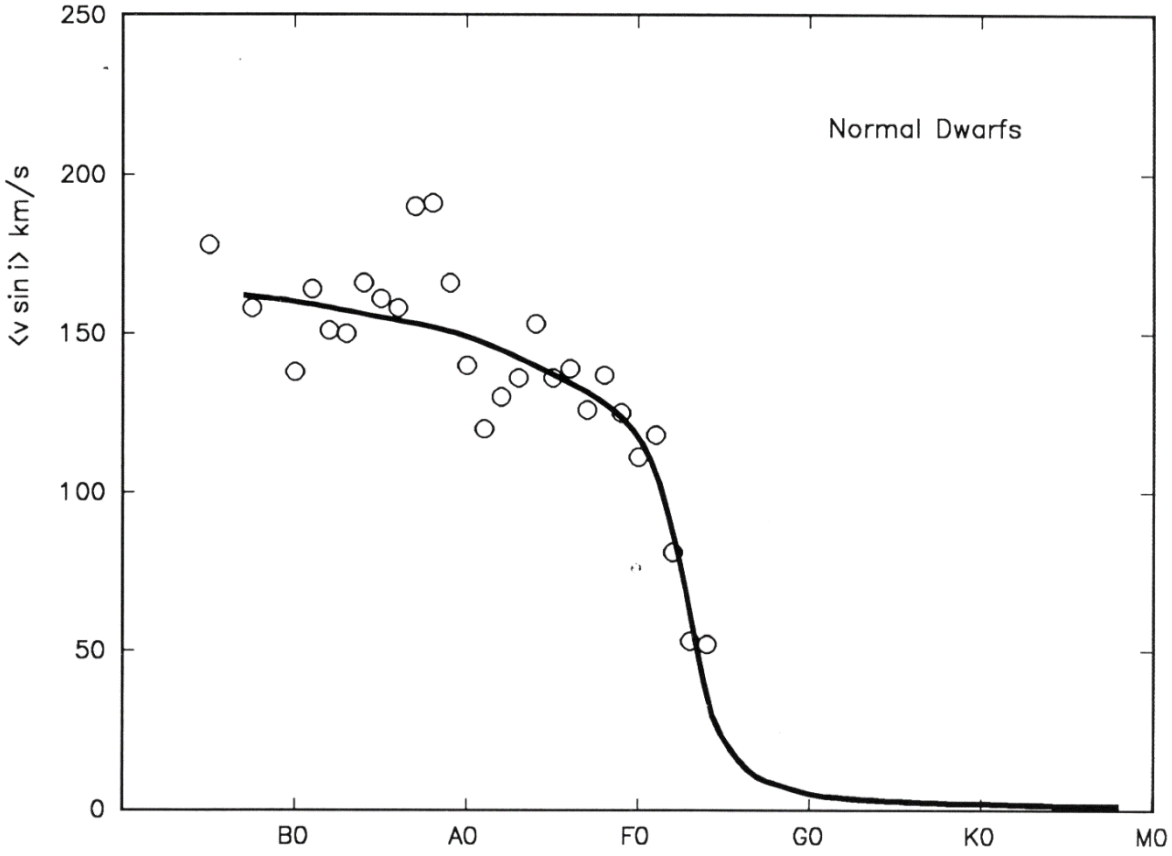

Fig. 17.16. The average rotation rates are shown for spectral intervals as a function of spectral type. (Data are from Uesugi and Fukuda (1982), Soderblom (1983), and Gray (1982b, 1984b).)

- ✓ Giants and supergiants rotate slowly because of angular momentum conservation.

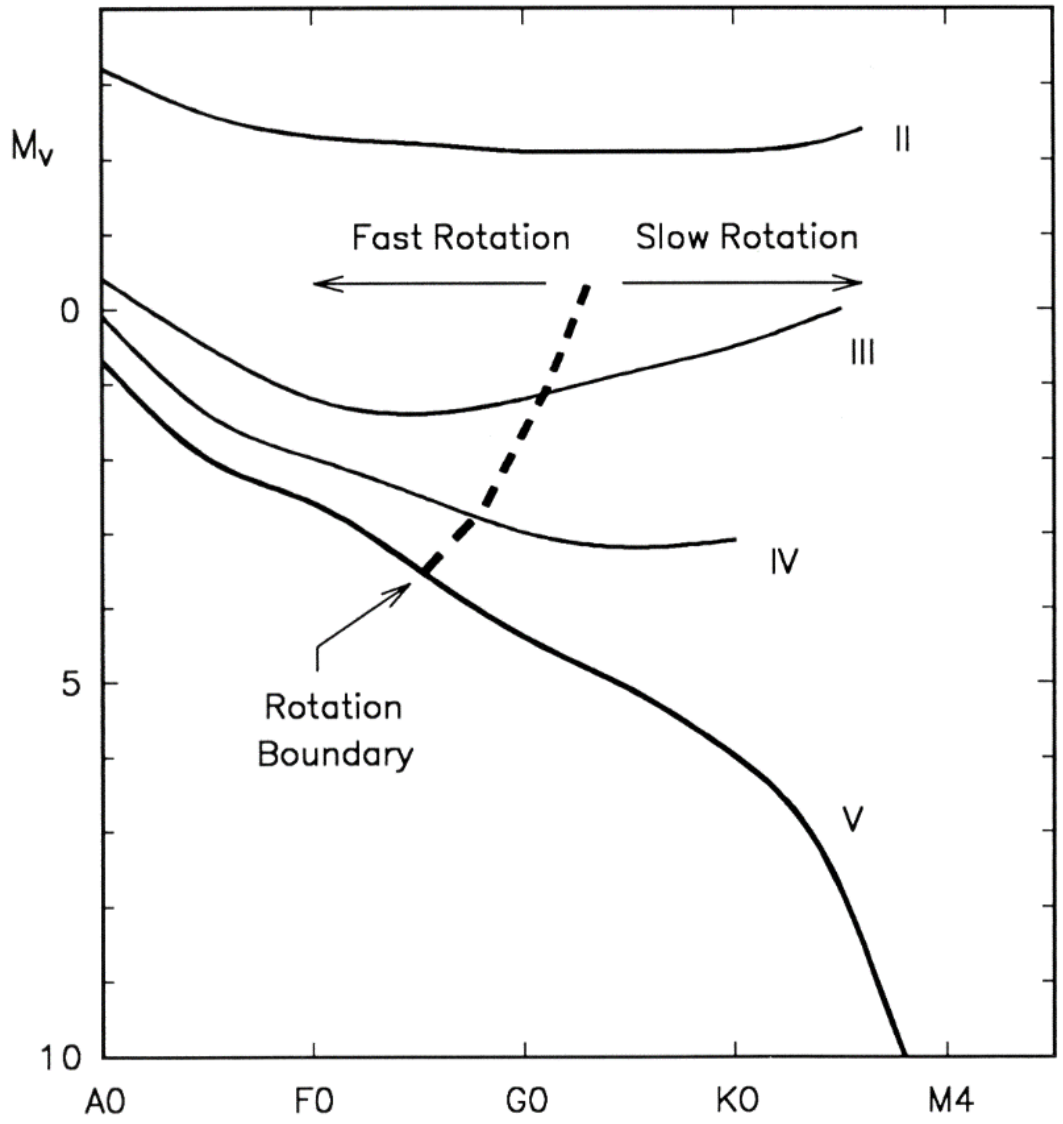

Fig. 17.21. The rotation boundary separates fast rotation from slow rotation.

ON THE EVOLUTION OF THE MAIN-SEQUENCE STARS

M. SCHÖNBERG[1] AND S. CHANDRASEKHAR

ABSTRACT

The evolution of the stars on the main sequence consequent to the gradual burning of the hydrogen in the central regions is examined. It is shown that, as a result of the decrease in the hydrogen content in these regions, the convective core (normally present in a star) eventually gives place to an isothermal core. It is further shown that there is an upper limit (~ 10 per cent) to the fraction of the total mass of hydrogen which can thus be exhausted. Some further remarks on what is to be expected beyond this point are also made.

$$\frac{M_c}{M} \approx 0.37 \left(\frac{\mu_e}{\mu_c}\right)^2$$ (~ 10-15% in reality)

Radius r, ratio P_g/P of gas pressure computed from the perfect gas law to the actual pressure with degeneracy included, temperature T, net luminosity L_r, and hydrogen abundance X are shown as functions of fractional mass M_r/M in the range 0 to 0.38. The distribution of L_r is a step function rising from zero to maximum scale with the initial rise in X. The lower limit of the ordinate is zero for all variables. The upper limits, given in the figure, are 1 $R_\odot$ (with $R_\odot = 6.96 \times 10^{10}$ cm; however, the total radius is 6.1784 $R_\odot$), unity for the ratio of pressures, central density ρ_c (gm cm^{-3}), central temperature T_c (°K), total luminosity L (units of $L_\odot = 3.86 \times 10^{33}$ erg sec^{-1}), and hydrogen abundance $X = 0.693$. The central pressure (not shown) is 6552.2 dyne cm^{-2}. The time is measured from the initial model calculated for the pre–main-sequence phase (see Section 2). [Adapted from I. Iben, Jr., 1967 (326).]

Envelope expands and cools

Present Sun

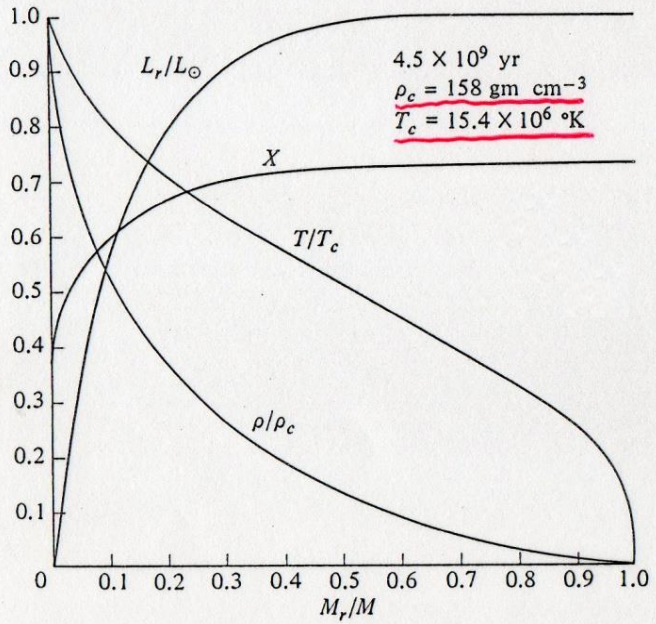

Fig. 7-11A A Model Solar Interior. Density relative to the central density ρ/ρ_c, temperature relative to central temperature T/T_c, net luminosity relative to total luminosity $L_r/L_\odot$, and hydrogen abundance X are shown as functions of fractional mass M_r/M. The chemical composition is $X = 0.730$, $Y = 0.245$, and $Z = 0.025$. The age is 4.5×10^9 years. [After S. Torres-Peimbert, E. Simpson, and R. K. Ulrich, 1969 (329).]

$X_c = 0.376$

Sun on the main sequence

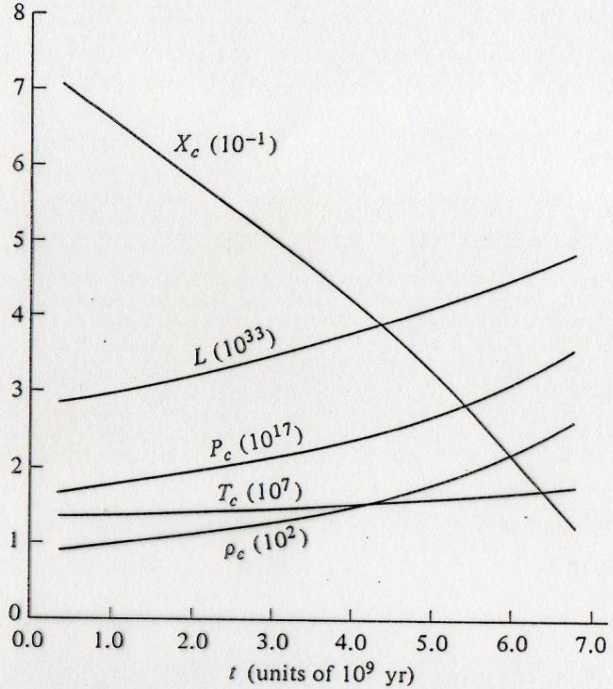

Fig. 7-11B The Evolution of the Sun during 7 Billion Years. Total luminosity L and central values of pressure P_c, temperature T_c, density ρ_c, and hydrogen abundance X_c are shown as functions of time t, which is measured from the initial (homogeneous) state for which the composition is $X = 0.730$, $Y = 0.245$, and $Z = 0.025$. The power of ten by which each value must be multiplied is indicated in parentheses. The values of P_c, ρ_c, and L are expressed in cgs units, and T_c is expressed in degrees Kelvin. [After S. Torres-Peimbert, E. Simpson, and R. K. Ulrich, 1969 (329).]

Evolutionary track of a $1M_\odot$ model ($Z = 0.015$, $Y = 0.275$) during gravitational contraction and central and shell hydrogen-burning phases

Iben 2013

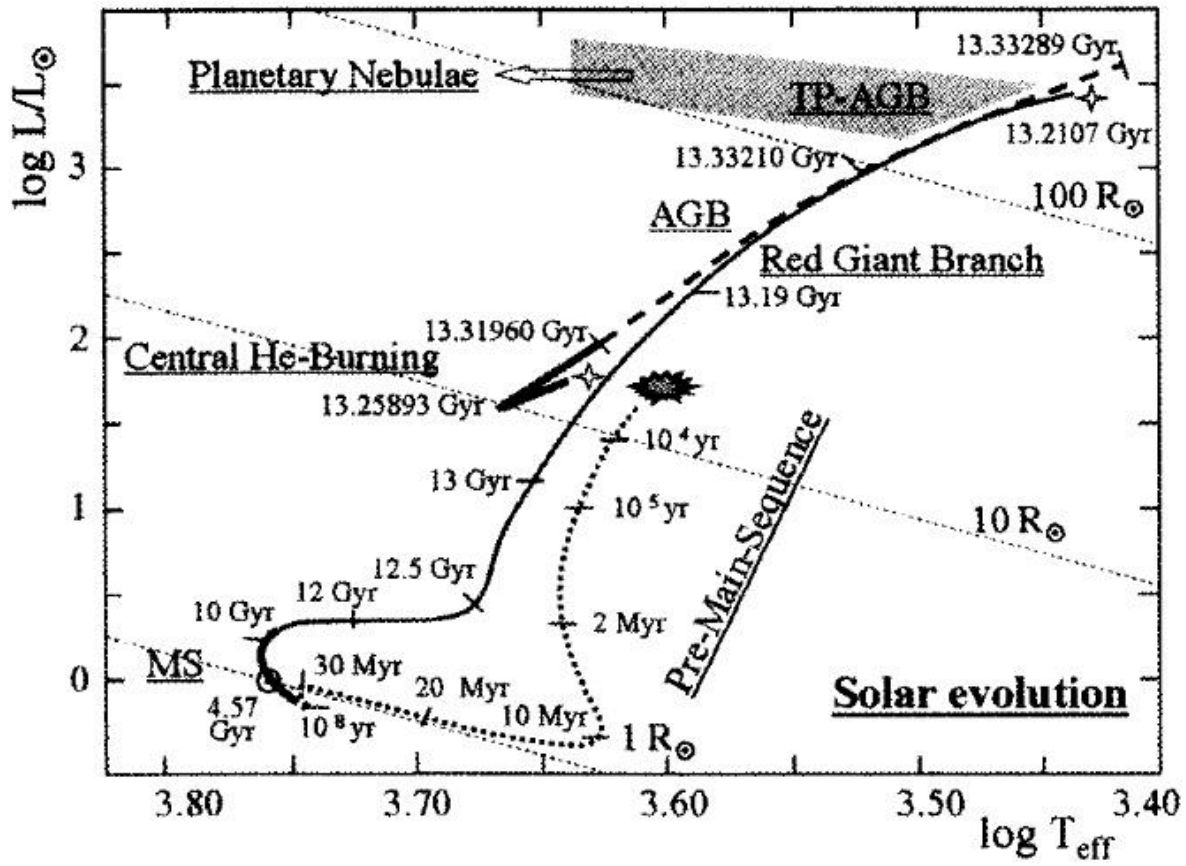

Figure 3.1. The evolution of the Sun. The evolution track of a solar-mass star is shown in the HR diagram from its formation to its death as a planetary nebula. Time is indicated at different steps along the track. The two 4-branch stars correspond to the helium flash and to the subsequent rapid rearrangement of the structure of the star. *From Maeder (2009), data from Corinne Charbonnel.*

Main Sequence Phase = core H burning

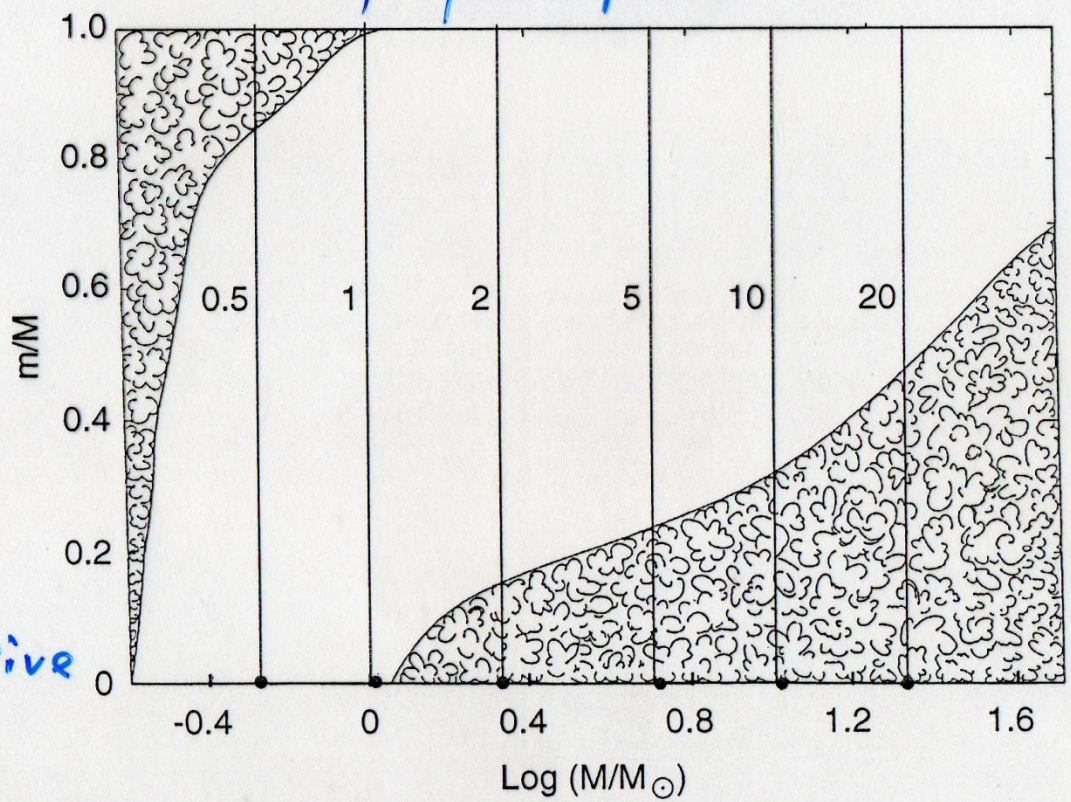
Evidence of thermonuclear reactions at a star's center, i.e., stellar evolution

- (solar) neutrinos
- heavy elements in evolved stars
  (isotope ratios ± YSOs)

  'dredge-up' ← convective zone
  to bring processed materials to surface
- Stars "disappear", e.g., supernovae

M ↑ ⇒ smaller outer convective zone

For the Sun, convective zone only 2% solar mass below the photosphere



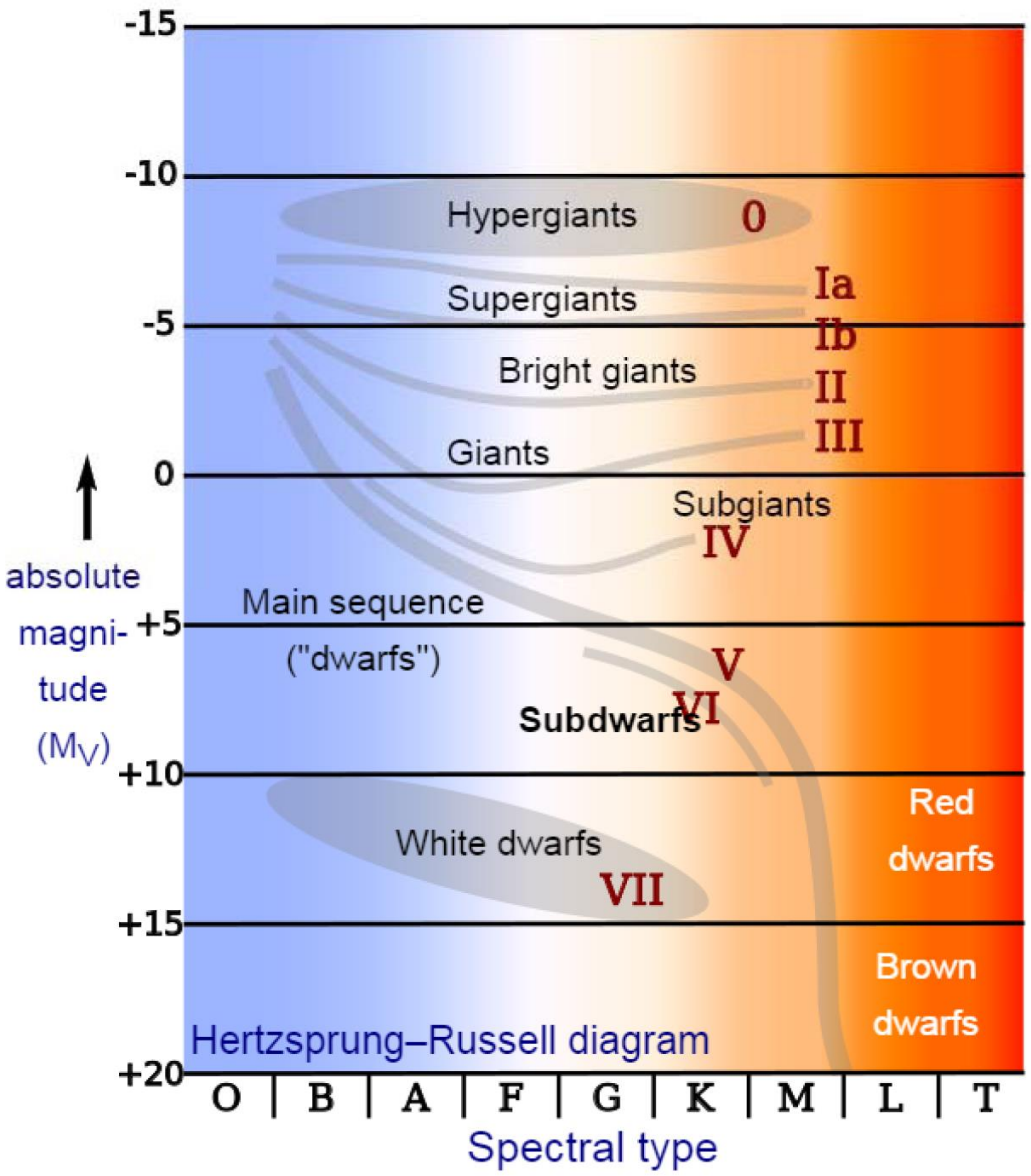
$M \lesssim 0.3\ M_\odot$

Star fully convective

Figure 8.4 The extent of convective zones (shaded areas) in main-sequence star models as a function of the stellar mass [adapted from R. Kippenhahn & A. Weigert (1990), *Stellar Structure and Evolution*, Springer-Verlag].

Subdwarfs: The Pop II Main Sequence

- Luminosity class VI
- 1.5 to 2 mag fainter than a Pop I MS stars o the same spectral type
- Low metallicity → low opacity → (UV excess) → low radiation pressure, so smaller, hotter for the same stellar mass



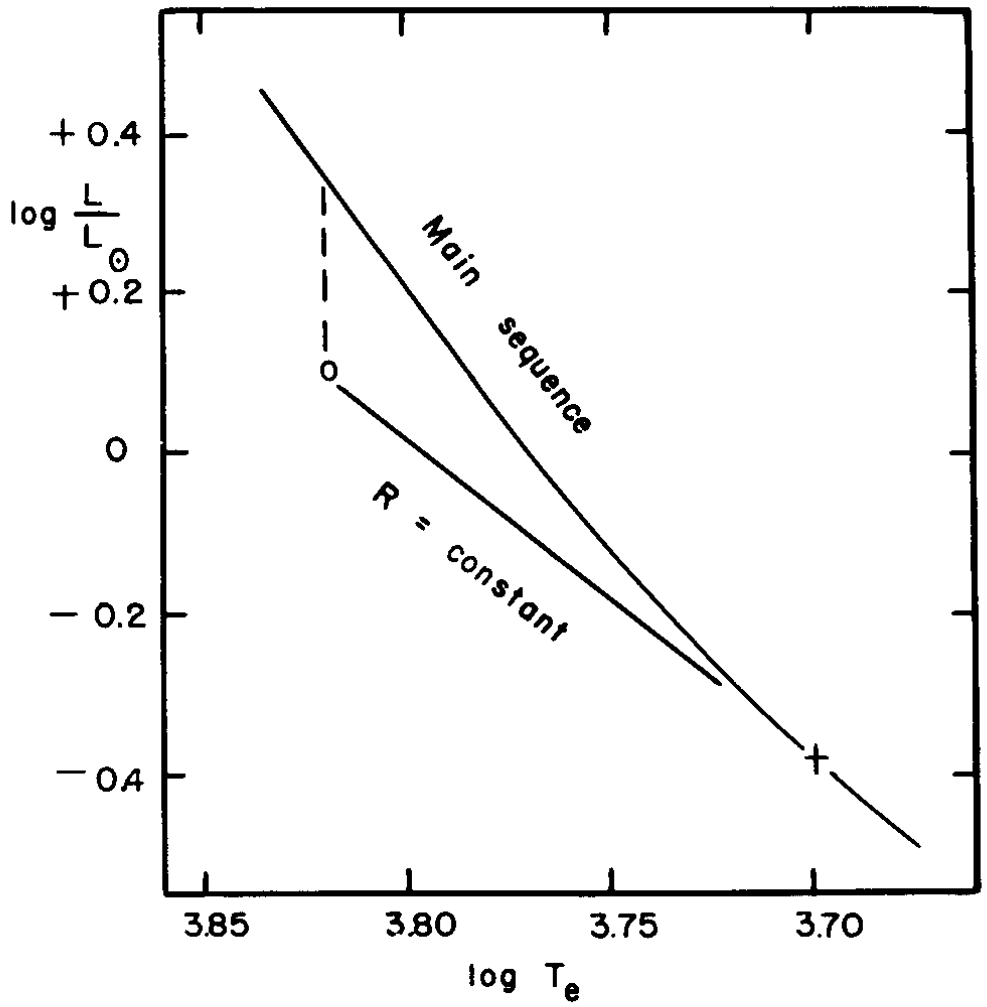


Fig. 17.1. Relation of subdwarfs to the main-sequence in the Hertzsprung-Russell diagram.
